ABSTRACT

Acute myeloid leukemia (AML) is an aggressive and frequently fatal hematological malignancy. *Chryseobacterium* spp. are Gram-negative bacilli which is found in soil and water. In hospital environments, they are isolated from water systems and wet medium. Infections caused by *Chryseobacterium indologenes* are rare. Risk factors for *C. indologenes* can be underlying disorders, immunosuppression and indwelling catheters. We reported a patient with pneumoniae infection due to *C. indologenes* and diagnosed with acute myeloid leukemia. We aimed to present this case to emphasize the importance of infections due to rare pathogens in patients with hematological malignities and appropriate treatment.

Key Words: *C. indologenes*, Acute Myeloid Leukemia, Gram Negative Bacilli, Pneumoniae

INTRODUCTION

Acute myeloid leukemia (AML) is an aggressive and frequently fatal hematologic malignancy (Fathi and Chen, 2011). The disease in which too many immature white blood cells that are not lymphoblasts are found in the bone marrow and blood (National Cancer Institute).

Chemotherapy administration and immunosuppressive treatment in AML patients are more prone to infections. Besides these patients are undergoing invasive procedures and indwelling catheters which are also risk factors for infection as well.

*Chryseobacteria* are Gram negative bacilli and nonfermentative. This is an unusual human pathogen mostly isolated from various sources in the hospital setting. Most infections were found in hospitalized patients with underlying disorders and indwelling catheters. Although they possess less virulence, they are resistant to many antimicrobial agents (Bhuyar et al., 2012).

We aimed to present this case to emphasize the importance of infections due to rare pathogens in patients with hematological malignities and appropriate treatment.

CASES

32 year old male patient was admitted to a tertiary care in Izmir province. The complete blood count (CBC) report showed 195000/mm³ leukocytes, Hb: 6.8 g/ml, platelet: 195000/mm³. Peripheral smear revealed 92% blast formation. Bone marrow aspiration and biopsy was carried out. He was diagnosed as acute myeloid leukemia (AML). His leukocyte count was 116100/mm³, Hb:8.2 g/dl and platelet count was 116100/mm³. Hydroxy urea 3g/day was initiated. Then he was admitted to Izmir University School of Medicine Medicalpark Hospital Department of Hematology.

The physical examination of the patient was normal except bilateral inguinal LAP and 1 cm hepatomegaly. Fever was not detected. The patient was administered cytosine-arabinoside/daunorubicin (200mg/m²/day). On the sixth day of hospitalization, the patient developed neutropenic fever. Blood, and urine cultures were taken due to neutropenic fever. Sputum culture was taken because of cough complaint on the sixth day. The Gram stain of the sputum culture showed polymorphonuclear leukocytes and Gram negative bacilli. The sputum was cultivated on blood agar, eosin methylene blue agar and chocolate agar. Lung X-ray image revealed no pathological symptoms (Figure 1). Prophylactically valacyclovir, posaconazole and levofloxacin treatment were initiated. Neutropenic fever continued on the eighth day.
Case Report

Urine culture did not report growth. The colonies of the sputum culture were smooth, circular, yellow-pigmented on sheep blood agar (Figure 2). The identification and the antimicrobial susceptibility was studied by automatized Vitek system version 2.0 (Biomerieux, France). The isolate was identified as *Chryseobacterium indologenes*. The strain was susceptible to quinolones. The patient continued quinolone treatment. Enviromental cultures were taken and no growth was detected after two days. The patient was not considered as colonisation due to this report and immunosuppression. Urine, blood and sputum cultures were repeated. Neutropenic fever continued on the tenth day. The second sputum culture reported *C.indologenes*. On the twelveth day cough and sputum symptoms continued. Simultaneously blood, urine and sputum cultures were taken. Third sputum culture also reported *C.indologenes*. Tazobactam/piperacillin was added to treatment according to antibiotic susceptibility pattern because of cough and sputum symptoms continued. During this period the patient was interpreted as pneumoniae due to elonged neutropenia which did not reveal radiological findings. First blood culture was negative. Second blood culture reported Coagulase Negative Staphylococci. Teicoplanin (800mg/day) was initiated. Control cultures did not reveal any pathological results. On the eighteenth day antibiotic therapy continued. All of the cultures were negative. Neutropenic fever was partially controlled. On the twentieth day the fever was partially controlled and neutropenic period was finished. On the twenty second day the general status of the patient was fine. Antibiotic therapy was discontinued. At the twentysixth day %2 blast formation was detected in control bone marrow aspiration and total remission was achieved and was discharged. The patient had allogenic bone marrow transplantation. The transfer was successfully done.

RESULTS AND DISCUSSION

Discussion

Chemotherapy administration and immunosuppressive treatment in AML patients are more prone to infections. Besides these patients are undergoing invasive procedures and indwelling catheters which are also risk factors for infection as well. Opportunistic and rare infectious pathogens may cause serious problems in these patients. *C. indologenes* does not exist in human flora. They can live in in the hospital environment. They can stay in wet surfaces and can act as potential sources of infection (Calderon et al., 2011).

Bayraktar et al reported *Chryseobacterium indologenes* isolated from blood samples from a 5-month-old infant with bloodstream infection. Environmental sampling was performed. The infant was infected by this water (Bayraktar et al., 2007). In our case report there was no cross contamination and the strain was not isolated from enviromental cultures.

Calderon et al reported a case of ventilator-associated pneumonia caused by *C. indologenes* in a newborn baby boy with congenital heart disease. The child recovered with piperacillin-tazobactam (Calderon et al., 2011). Our patient was an adult individual with an underlying hematological disorder and immunosuppression may be a major predisposing factor. Our patient was also treated by tazobactam/piperacillin. In our case report there was not an application of mechanical ventilation.

Chou et al., (2011) reported ten patients with *C. indologenes* bacteremia. The authors think that this microorganism needs to be considered in patients with bacteremia and hospitalized for a long time in intensive care units (Chou et al., 2011).

Christakis et al reported a case of bacteremia not related with a indwelling catheter and caused by *C. indologenes* in a patient with a solid tumor. The patient was not in a neutropenic status and recovered with piperacillin-tazobactam. The authors emphasized that *C. indologenes* infections can take place in patients without having a catheter (Christakis et al., 2005). In our case the patient also had malignity and the patient had piperacillin-tazobactam treatment.

de Souza Ferreira et al., (2010) reported a case of *C. indologenes* isolated from the tracheal aspirate in a patient on prolonged mechanical ventilation. The patient was a 30 year old male and he had high fever not resolved with antipyretics followed by dizziness and dyspnea. He had no respiratory symptom pathology. In our case we reported *C.indologenes* isolated from consecutively collected sputum cultures and the patient...
had no cough or expectoration at the admission; but the fever continued. On the sixth day of his admission the patient developed cough and sputum. We also administered levofloxacin treatment relevant with the antibiotic susceptibility pattern and tazobactam/piperacillin was also added according to antimicrobial susceptibility pattern.

We reported a *C.indologenes* pneumoniae infection in a patient with acute myeloid leukemia. We discussed this case in light of current literature. Patients with hematological malignancies and under immunosuppressive therapy are under the risk of opportunistic infections. In our case the patient had no radiological sign; but he developed cough and sputum. The sputum culture revealed *C.indologenes*; and the patient was treated according to antibiotic susceptibility pattern. In these cases the isolation of the pathogen and appropriate treatment are important. This case showed that *C. indologenes* is a pathogen that has to be paid attention and it can lead to severe infections.
